- 1. AC or DC motor type with a 0  $\Omega$  winding resistance assumed.
- 2. The first value is for a stationary AC or DC motor. The second value is for a moving AC motor.
- 3. De-rate at temperatures above 25°C ambient.
- 4. Amplifier power dissipation is calculated as (Vbus Vout)  $\cdot$  lout for each phase. A 40B configuration that drives 1 A into 0  $\Omega$  results in 40 W of power dissipation in the amplifier.
- 5. The amplifier has peak power-limiting circuitry to protect itself from damage. The power limiting bit in the drive status word indicates if this has occurred.
- 6. This specification depends on the motor supply voltage, the motor speed, and motor resistance. Contact an Aerotech sales engineer for more information.
